$$\alpha_D = \frac{8\pi}{9} \sum_{\nu} \frac{B(E1; 0^+_{\mathrm{g.st.}} \to 1^-_\nu)}{E_{1^-_\nu}}$$

REALIZATION OF QRPA

Realization of QRPA

The starting point of the method is the HF-BCS calculations of the ground state, where spherical symmetry is assumed for the ground states. The continuous part of the single-particle spectrum is discretized by diagonalizing the HF Hamiltonian on a harmonic oscillator basis.

J. P. Blaizot and D. Gogny, **Nucl. Phys.** A284, **429 (1977)**.

The residual interaction in the particle-hole channel V_{res}^{ph} and in the particle-particle channel V_{res}^{pp} can be obtained as the second derivative of the energy density functional $\mathcal{H}$ with respect to the particle density ρ and the pair density $\tilde{\rho}$, respectively.

$$V_{res}^{\mathrm{ph}} \sim \frac{\delta^2 \mathcal{H}}{\delta \rho_1 \delta \rho_2} \quad V_{res}^{\mathrm{pp}} \sim \frac{\delta^2 \mathcal{H}}{\delta \tilde{\rho}_1 \delta \tilde{\rho}_2} .$$

G. T. Bertsch and S. F. Tsai, **Phys. Rep.** 18, **125 (1975)**.

Realization of QRPA

We employ the effective Skyrme interaction in the particle-hole channel

$$V(\vec{r}_1,\vec{r}_2)=t_0\left(1+x_0\hat{P}_\sigma\right)\delta(\vec{r}_1-\vec{r}_2)+\frac{t_1}{2}\left(1+x_1\hat{P}_\sigma\right)\left[\delta(\vec{r}_1-\vec{r}_2)\vec{k}^2+\vec{k}'^2\delta(\vec{r}_1-\vec{r}_2)\right]$$
$$+t_2\left(1+x_2\hat{P}_\sigma\right)\vec{k}'\cdot\delta(\vec{r}_1-\vec{r}_2)\vec{k}+\frac{t_3}{6}\left(1+x_3\hat{P}_\sigma\right)\delta(\vec{r}_1-\vec{r}_2)\rho^\alpha\left(\frac{\vec{r}_1+\vec{r}_2}{2}\right)$$
$$+iW_0(\vec{\sigma}_1+\vec{\sigma}_2)\cdot\left[\vec{k}'\times\delta(\vec{r}_1-\vec{r}_2)\vec{k}\right].$$

T. H. R. Skyrme, **Nucl. Phys. 9, 615 (1959).**

D. Vautherin and D. M. Brink, **Phys. Rev. C5, 626 (1972).**

The Hamiltonian includes the pairing correlations are generated by the density-dependent zero-range force in the particle-particle channel

$$V_{pair}(\vec{r}_1,\vec{r}_2)=V_0\left(1-\eta\frac{\rho(r_1)}{\rho_{sat}}\right)\delta(\vec{r}_1-\vec{r}_2),$$

where ρ_{sat} is the nuclear saturation density; η and V_0 are model parameters. For example, $\eta=0$ and $\eta=1$ are the case of a volume interaction and a surface-peaked interaction, respectively.

Realization of QRPA

We introduce the phonon creation operators

$$Q^{+}_{\lambda\mu i}=\frac{1}{2}\sum_{jj'}\left[X^{\lambda i}_{jj'}\,A^{+}(jj';\lambda\mu)-(-1)^{\lambda-\mu}Y^{\lambda i}_{jj'}\,A(jj';\lambda-\mu)\right],$$

$$A^{+}(jj';\lambda\mu)=\sum_{mm'}C^{\lambda\mu}_{jm\,j'm'}\alpha^{+}_{jm}\alpha^{+}_{j'm'}.$$

The index λ denotes total angular momentum and μ is its z-projection in the laboratory system. One assumes that the ground state is the QRPA phonon vacuum $|0\rangle$ and one-phonon excited states are $Q^{+}_{\lambda\mu i}|0\rangle$ with the normalization condition

$$\langle 0|[Q_{\lambda\mu i},Q^{+}_{\lambda\mu i'}]|0\rangle=\delta_{ii'}.$$

Making use of the linearized equation-of-motion approach one can get the QRPA equations

$$\begin{pmatrix}\mathcal{A} & \mathcal{B}\\ -\mathcal{B} & -\mathcal{A}\end{pmatrix}\begin{pmatrix}X\\ Y\end{pmatrix}=\omega\begin{pmatrix}X\\ Y\end{pmatrix}.$$

Solutions of this set of linear equations yield the one-phonon energies ω and the amplitudes X, Y of the excited states.

RESULTS AND DISCUSSION

Details of calculations

The dipole transition probabilities can be expressed as

$$B(E1; 0^+_{gs} \to 1^-_i) = \left| e^{(\mathrm{n})}_{eff} \langle i | \hat{M}^{(\mathrm{n})} | 0 \rangle + e^{(\mathrm{p})}_{eff} \langle i | \hat{M}^{(\mathrm{p})} | 0 \rangle \right|^2 ,$$

where $\hat{M}^{(\mathrm{p})} = \sum_i^Z r_i Y_{1\mu}(\hat{r}_i)$ and $\hat{M}^{(\mathrm{n})} = \sum_i^N r_i Y_{1\mu}(\hat{r}_i)$. The spurious 1^- state is excluded from the excitation spectra by introduction of the effective neutron $e^{(\mathrm{n})}_{eff} = -Z/A\, e$ and proton $e^{(\mathrm{p})}_{eff} = N/A\, e$ charges.

For our systematic analysis of the electric dipole polarizability, we employ 21 Skyrme interactions: LNS, SAMi, SGII, SIII, SK255, SkI2, SkI3, SkI5, SkM*, SkP, SkT5, SkT6, SkT7, SkX, SLy4, SLy5, SVbas, SVmas07, SVmas08, SVmas10, and SVmin. The choice of these parameterizations is due to the large range of values for the effective nucleon mass $m^* = 0.58-1.00$ and the symmetry energy at saturation density $J = 26.8-37.4$ MeV.

Pearson correlation coefficient

In statistics, the Pearson correlation coefficient (r) is a measure of linear correlation between two sets of data: (a_1, b_1), ..., (a_N, b_N). The Pearson coefficient calculate as

$$r = \frac{\sum_{i=1}^{N}(a_i - \bar{a})(b_i - \bar{b})}{\sigma_a \sigma_b},$$

where $\bar{a}$, $\bar{b}$ represent the mean values and σ_a, σ_b the root mean square of the sample. The coefficient r always has a value between -1 and $+1$. Correlations equal to -1 or $+1$ correspond to data points lying exactly on a line. In fact, we may transform a_k to $\tilde{a}_k$, where

$$\tilde{a}_k = r\frac{\sigma_a}{\sigma_b}(b_k - \bar{b}) + \bar{a}.$$

For any value of the coefficient r, the value of $\tilde{a}_k$ is the best linear approximation for a_k.

The nuclear symmetry energy J

One of the key properties of nuclear matter is the symmetry energy (J), which is particularly important in modeling nuclear matter and finite nuclei because it probes the isospin part of the Skyrme interaction. It is defined as

$$J(\rho) = \frac{\hbar^2}{6m}\left(\frac{3\pi^2}{2}\right)^{2/3}\rho^{2/3} - \frac{1}{8}t_0\left(2x_0+1\right)\rho - \frac{1}{24}\left(\frac{3\pi^2}{2}\right)^{2/3}\rho^{2/3}\left[3t_1x_1 - t_2(4+5x_2)\right] - \frac{1}{48}t_3\left(2x_3+1\right)\rho^{\alpha+1}.$$

Saturation properties of a few Skyrme parametrizations used in this work.

Estimation of the symmetry energy J

We carried out a theoretical analysis of the recently measured $\alpha_{\rm D}$ and $\Delta R_{\rm np}$ in ^{48}Ca, ^{68}Ni, and ^{208}Pb to extract information about the symmetry energy, by using a strong correlation between $\alpha_{\rm D} J$ and $\Delta R_{\rm np}$. Combining the experimental data and the RPA theory constraints yields the interval of $J = 30 - 37$ MeV†.

† The current global average $J = 31.60 \pm 0.92 \pm 2.66$ MeV obtained using the 28 analyses of terrestrial nuclear experiments and astrophysical observations [*B. A. Li and X. Han*, Phys. Lett. B727, 276 (2013)]

Conclusions

The Skyrme RPA calculations have been performed for the electric dipole response in the magic nuclei ^{16}O, ^{40,48,60}Ca, ^{56,68,78}Ni, ^{90}Zr, ^{100,132}Sn and ^{208}Pb. We have computed the nuclear dipole polarizability (α_{D}) and neutron skin thickness (ΔR_{np}) of these nuclei using a broad set of Skyrme functionals. It is shown that the neutron skin thickness is correlated the product of the electric dipole polarizability and the symmetry energy (J) at saturation density.

We carried out a theoretical analysis of the recently measured α_{D} and ΔR_{np} in ^{48}Ca, ^{68}Ni, and ^{208}Pb to extract information about the symmetry energy, by using a strong correlation between α_{D} and ΔR_{np}. Combining the experimental data and the RPA theory (using a broad set of Skyrme functionals) constraints yields the interval of $J{=}30{-}37$ MeV.
